Nucleic acid degradation mediated by the exosome-like complexes is important for regulation of gene expression. The exosome may be involved in transcriptional regulation by removing aberrant RNA

molecules. It has been speculated that the exosome may serve as a de novo primase. There are three known exosome components, RRP8, RRP46 and Dis3. Mutations in any one of these exosome components lead to similar phenotypes. Biochemical purification of the exosome complex should lead to the isolation of these three proteins. These proteins are thought to be associated with the RNA polymerase II-associated complexes (PAFs), suggesting that the exosome may be a recycling factor involved in the transcription cycle. The exosome

is thought to act by degrading RNA molecules that are retained in the cells by virtue of illegitimate splicing 3a67dffeec
